Weekly Report 4 - DBSCAN

Ganji Varshitha AI20BTECH11009

Introduction

DBSCAN stands for Density-Based Spatial Clustering of Applications with Noise. It is a density based unsupervised learning algorithm which clusters data into arbitrary shape.

Algorithm

It assumes clusters are dense regions separated by regions of low density. Hence, it identifies those regions of high densities.

Key terms

- **Density**: The number of points within a specific radius Eps.
- Epsilon or Eps: The radius of circle around each data point to check the density.
- Core point: A point is considered Core point if it has more than specific number of points(MinPts) within Eps.
- Border point: A point is considered Border point if it has less than MinPts but grater than 1 point within Eps.
- Noise: A point which does not have any points within Eps is considered noise.

Reachability and Connectivity

Reachability states if a data point can be accessed from another data point directly or indirectly, whereas Connectivity states whether two data points belong to the same cluster or not.

In the algorithm, any points can be referred as:

- Directly density reachable : An object q is directly density-reachable from object p if q is within the ϵ Neighbourhood of p and p is a core point.
- **Density reachable**: An object p is density-reachable from q w.r.t ϵ and MinPts if there is a chain of objects p_1, \dots, p_n , with $p_1 = q, p_n = p$ such that p_{i+1} is directly density-reachable from p_i w.r.t ϵ and MinPts for all $1 \leq i \geq n$

• **Density Connectivity**: Object p is density-connected to object q w.r.t ϵ and MinPts if there is an object r such that both p and q are density-reachable from r w.r.t ϵ and MinPts.

Algorithm 1 DBSCAN algorithm

```
clusterIndex = 0
for p in dataset do
   if p has label then
       continue
   end if
   if neighboursCount(p,\epsilon) \geq MinPts then
       p is a core point
       p.clusterId = clusterIndex
       for neighbour in neighbours (p, \epsilon) do
          if neighbour has no clusterId then
              neighbour.clusterId = clusterIndex
              if neighbour is core point then
                 Visit all neighbours
              end if
          end if
       end for
   else
       p is a noise point
   end if
end for
clusterIndex++
```

Key points

- It is density based and used euclidean distance as distance metric.
- The algorithm is very sensitive to the parameters Epsilon(Eps) and MinPts.

Choosing MinPts

Having domain knowledge is important to find MinPts. Also, its obvious that MinPts can't be 1 and should be at least number of dimensions increased by 1.

Choosing Epsilon:

This is calculated using K-distance graph which means plotting the sorted distance between a point and its Kth nearest neighbour for all points in the dataset. The distance in the graph where the maximum curvature occurs is taken as Eps.

- The algorithm is robust to outliers
- Algorithm does not require to specify number of clusters.
- Algorithm may not work in high dimensional data and varying density clusters.

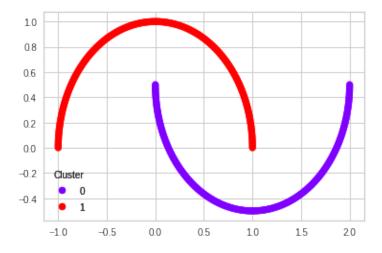

Python Implementation Example

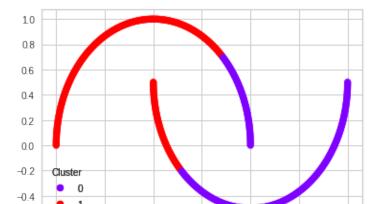

```
class DBSCAN():
    def __init__(self,min_samples,eps,dataset):
    ',',Constructor','
      self.min_samples = min_samples
      self.eps = eps
      self.dataset = dataset
    #Auxilary functions
    def neighbours(self,pt):
      neighbours = []
      point = self.dataset[pt]
12
13
      for y_idx,y_pt in enumerate(self.dataset):
14
        norm = np.linalg.norm(y_pt - point)
        if norm <= self.eps and y_idx != pt:</pre>
16
          neighbours.append(y_idx)
17
      return neighbours
18
19
    def check_neighbours(self,pt_id,cluster_idx,cluster_to_pt):
20
      for neighbour in self.neighbours(pt_id):
        if cluster_to_pt[neighbour] == -1:
22
          cluster_to_pt[neighbour] = cluster_idx
23
          if len(self.neighbours(neighbour))>=self.min_samples:
24
             self.check_neighbours(neighbour,cluster_idx,cluster_to_pt)
26
27
    #Actual DBSCAN Code
28
    def clustering(self):
29
      cluster_idx = 0
30
      #Initialising cluster indices to -1 for the whole dataset
31
      cluster_to_pt = [-1]*len(self.dataset)
      for pt_idx,pt in enumerate(self.dataset):
33
        if cluster_to_pt[pt_idx] != -1:
34
          continue
        if len(self.neighbours(pt_idx))>=self.min_samples:
36
          cluster_to_pt[pt_idx] = cluster_idx
37
          self.check_neighbours(pt_idx,cluster_idx,cluster_to_pt)
38
        cluster_idx +=1
39
40
      return cluster_to_pt
```
